A MINI-PROJECT REPORT SUBMITTED IN PARTIAL FULFILLMENT OF
THE REQUIREMENTS

ON

**”OBJECT RECOGNITION TO KEEP
SOCIAL DISTANCING NORMS IN CHECK”**

SUBMITTED BY

Abhinaba Chowdhury (510519007)
Abhiroop Mukherjee (510510109)
Debarghya Dey (510519087)
Jyotiprakash Roy (510519016)
Shrutantén (510519048)

UNDER THE GUIDANCE OF

DR. SAMIT BISWAS

(Academic Year: 2020-2021)

**INDIAN INSTITUTE OF ENGINEERING
SCIENCE AND TECHNOLOGY, SHIBPUR**
Howrah, West Bengal, India - 711103

**DEPARTMENT OF COMPUTER SCIENCE
AND TECHNOLOGY**

Certificate

It is certified hereby that this report, titled "*Object Recognition to keep Social Distancing Norms in check*", and all the attached documents herewith are authentic records of Abhinaba Chowdhury (510519007),
Abhiroop Mukherjee (510510109), Debarghya Dey (510519087), Jyotiprakash Roy (510519016), and Shrutanen (510519048) from the Prestigious Department of Computer Science And Technology of the Distinguished and Respected IIEST Shibpur under my guidance.

The works of these students are satisfies all the requirements for which it is submitted. To the extent of my knowledge, it has not been submitted to any different institutions for the awards of degree/diploma.

Dr. Samit Biswas
Asst. Professor

Dr. Sekhar Mandal
Head Of Department

ACKNOWLEDGEMENT

We, as the students of IIEST, consider ourselves honoured to be working with Dr. Samit Biswas. The success of this project would not have been possible without his useful insights, appropriate guidance and necessary criticism.

We would pass our token of token of gratitude to the Department of Computer Science And Technoogy as well for providing us with the opportunity to be able to tackle real world problems while improving our problem solving ability and thinking capacity by organising this project. We all have learnt quite a handful of new skills and are eager to use them henceforth as well.

Abhinaba Chowdhury (510519007)

Abhiroop Mukherjee (510510109)

Debarghya Dey (510519087)

Jyotiprakash Roy (510519016)

Shrutanten (510519048)

1 INTRODUCTION

1.1 Motivation

Coronaviruses are a group of related RNA viruses that cause diseases in mammals and birds. In humans and birds, they cause respiratory tract infections that can range from mild to lethal. Mild illnesses in humans include some cases of the common cold (which is also caused by other viruses, predominantly rhinoviruses), while more lethal varieties can cause SARS, MERS, and COVID-19.

With the increase in the spread of the dangerous and highly contagious **Novel Coronavirus** and the underlying disease caused by it, **COVID-19**, it is a requirement now more than ever to follow the social distancing norms set in place by the scientists and researchers.

But as we all know, India is a country with a not-so-small population, so it is pretty understandable and obvious that the law enforcement will not be able to actually enforce it on every single person. Therefore, new means of automata in place of actual individuals is a no brainer.

That is where we come in.

1.2 The Idea Behind The Project

The idea behind the working of this software was simple. The software just needed to be able to look at a live feed (or recorded footage) of a camera and know which of the people present in the footage are actually following the social distancing norms and which of them are not, and mark either one appropriately. That is where our journey to build a social distance checker started.

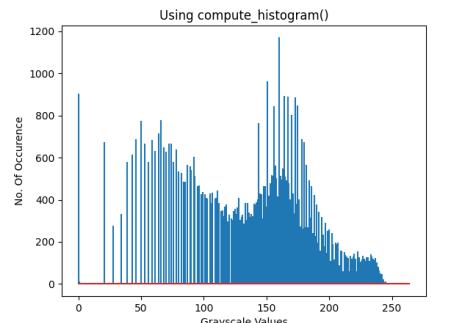

2 KNOWLEDGE REFINEMENT

Before we settled on the topic of object detection and started building this project, we got some practice, which was necessary since we were going to dip our toes in image processing.

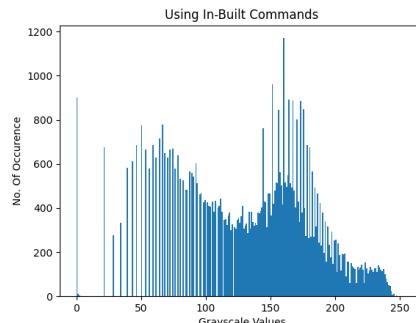

- We made histograms for grey-level images. This was done using both the OpenCV's `ravel()` function and our own implementation of it, called `compute_histogram()`

(a) Greyscale Image

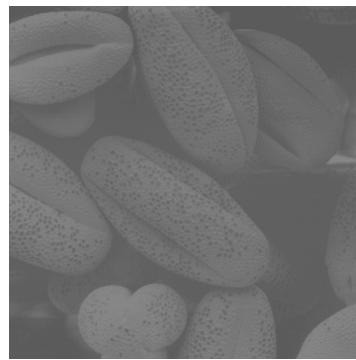

(b) histogram by `compute_histogram()`

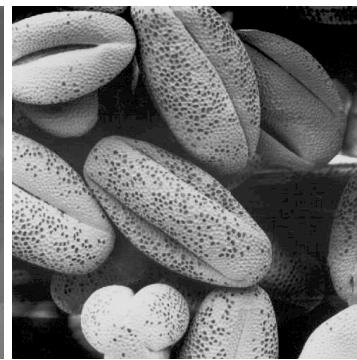

(c) histogram by in-built `ravel()`

Figure 1: Histogram of Greyscale Images

- Once that was over, we moved onto some Image Enhancement skills. Here we implemented noise reduction functions using mean, mode and median filters.

(a) Original Image

(b) Edited Image

Figure 2: Contrast Enhancement using Histogram Equalization

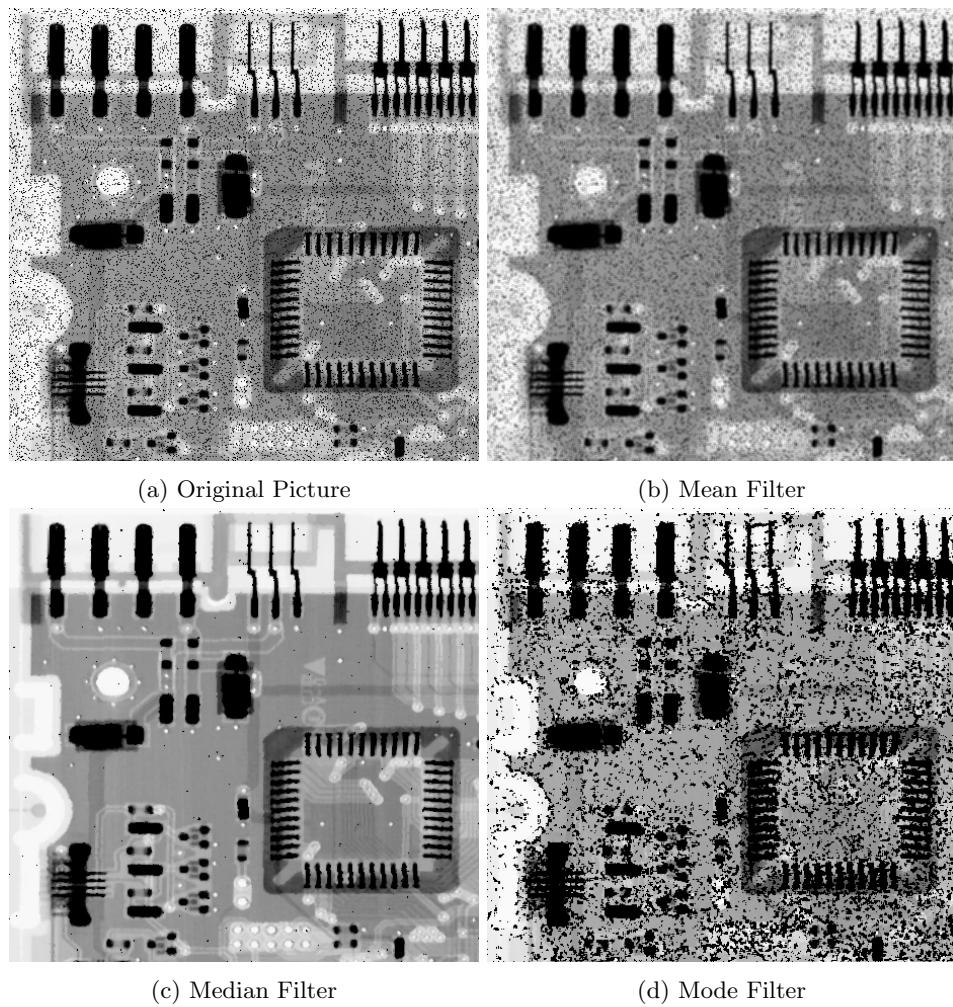

Figure 3: Mean, Median, and Mode Filter

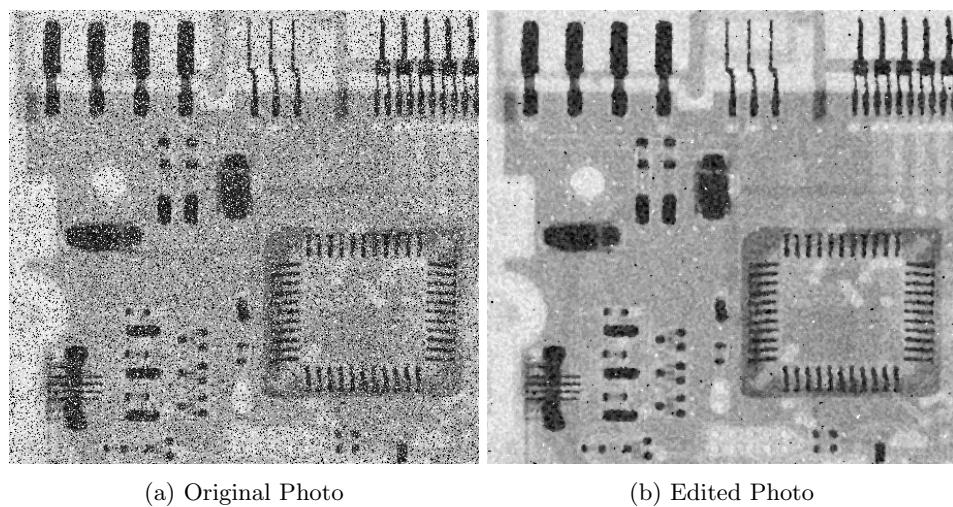

Figure 4: Salt And Pepper Noise Removal

- Then we implemented Otsu's Thresholding Algorithm [1] using minimization of within class variance approach.

```

1 import matplotlib.pyplot as plt
2 import cv2 as cv
3 import numpy as np
4
5 def otsu_threshold (img):
6     hist = cv.calcHist([img],[0],None,[256],[0,256])
7     hist_norm = np.divide(hist.ravel(),hist.sum())
8     q = hist_norm.cumsum()
9
10    bins = np.arange(256)
11
12    fn_min = np.inf
13    threshold = -1
14
15    for i in range(1,256):
16        p1,p2 = np.hsplit(hist_norm,[i])
17
18        q1 , q2 = q[i] , q[255]-q[i]
19
20        if q1 < 1.e-6 or q2 < 1.e-6:
21            continue
22
23        b1 , b2 = np.hsplit(bins,[i])
24
25        m1 = np.sum(p1 * b1)/q1
26        m2 = np.sum(p2 * b2)/q2
27
28        v1 = np.sum( ((b1 - m1)**2) * p1)/q1
29        v2 = np.sum( ((b2 - m2)**2) * p2)/q2
30
31        fn = v1*q1 + v2*q2
32
33        if fn < fn_min:
34            fn_min = fn
35            threshold = i
36
37    return threshold
38
39
40
41 img = cv.imread("input.jpg",0)
42
43 threshold = otsu_threshold(img)
44
45 a, img_my = cv.threshold(img,threshold,255,cv.THRESH_BINARY)
46 cv.imshow("My",img_my)
47
48 ret , img_os = cv.threshold(img,0,255,cv.THRESH_BINARY + cv.THRESH_OTSU)
49 cv.imshow("OS",img_os)
50
51 #cv.imwrite("output.jpg",img_my)
52
53 cv.waitKey(0)

```

3 PREREQUISITES

3.1 Outdoor Requirements

It is important to mention here that this is not a portable software that can be fed any footage and just be expected to work. There need to be some calibration measures taken to actually get this software working:

- Actually knowing the local social distancing norms
 - The minimum distance set for social distancing by the local government
- Finding a good position for the camera
 - The footage needs to be taken from a high enough place
- Knowing the required distance in pixels
 - This will depend on the position and angle of the camera's view

3.2 Hardware and Software Requirements

The tools used to build this software are platform independent. However, there are a few requirements needed to be fulfilled to get the program working. These are:

- Software Requirements
 - Python - 3.5 or above
 - OpenCV-Python - version 2 or above
 - YOLOv3 Configuration and Network Weights
 - Numpy
- Hardware Requirements
 - A GPU is optional yet recommended to get the best performance
 - If a GPU is not being used, the CPU need to be good enough

4 THE PROJECT

4.1 Software Used

The softwares used to build this *checker* are:

4.1.1 An Integrated Development Environment (IDE)

An Integrated Development Environment (IDE) is a software application that provides comprehensive facilities to computer programmers for software development. An IDE normally consists of at least a source code editor, build automation tools and a debugger. Some IDEs contain the necessary compiler, interpreter, or both; others, do not.

We used PyCharm as our IDE, as it was easy to set up and code

PyCharm is an integrated development environment (IDE) used in computer programming, specifically for the Python language. It is developed by the Czech company JetBrains. It provides code analysis, a graphical debugger, an integrated unit tester, integration with version control systems (VCSes), and supports web development with Django as well as data science with Anaconda.

4.1.2 Python

Python is an interpreted, high-level and general-purpose programming language. Python's design philosophy emphasizes code readability with its notable use of significant whitespace. Its language constructs and object-oriented approach aim to help programmers write clear, logical code for small and large-scale projects.

Why did we choose Python?

1. Python has an upper hand when it comes to software based on image recognition and object detection. Since it is the main objective of the project, choosing python was a given. Python has an upper hand when it comes to software based on image recognition and object detection. Since it is the main objective of the project, choosing python was a given.
2. Python is unbeaten when it comes to Machine Learning. Python has support for myriad machine learning libraries, such as OpenCV, the one being used here.
3. Python is comparatively easier to understand and learn. The syntax is clear and simple to read and write.
4. And just our overall experience of using python for years.

4.1.3 Google Colab

After working on the project for quite some time, we realized that we did not have enough hardware resources at our disposal to actually make the *checker* work smoothly. So we decided on shifting to Google Colab. Google Colab is an online iPython development environment similar to Jupyter Notebook. It uses CUDA acceleration to speed up processes, so we switched to it rather than continuing development

4.1.4 L^AT_EX

L^AT_EX was used to write this report. L^AT_EX is a software system for document preparation. When writing, the writer uses plain text as opposed to the formatted text found in "What You See Is What You Get" word processors like Microsoft Word or LibreOffice Writer.

4.2 The Program

4.2.1 Outline

The blueprint of this *checker* that we thought of initially:

1. Video Input

Need some way to handle video input coming through the camera feed

2. Processing

The input needs to be processed somehow

3. Detecting people

Need to identify people in the video feed

4. Measuring distance between each couple

Need to calculate the distance between every two persons

5. Mark the violations

Need to mark the ones that violate social distancing norms

4.2.2 Proceedings

How we proceeded with the outlines of the blueprint:

1. Video Input

This was easier than we expected it to be. We just had to get our hands on some recorded footage of somewhat populated areas. We refrained from using live footage because:

- It is tough to get our hands on the light footage of a security camera or the equivalent.
- If the checker worked on recorded footage, it would work on live footage as well.

The videos we ended up choosing:

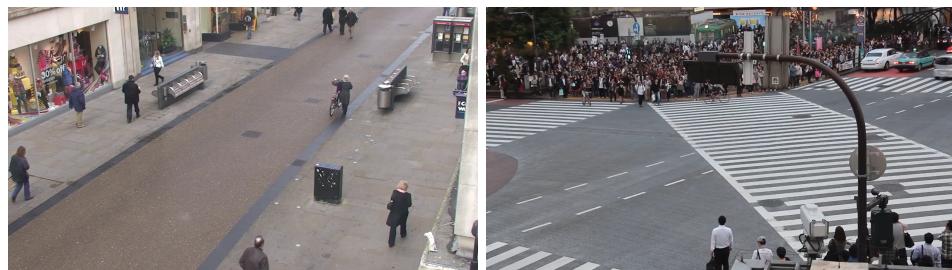

Figure 5: Still Pictures from Sample Videos

2. Processing

We used the OpenCV library for our video/image processing. It is a really handy library that can be used for image processing, object detection and many other purposes.

```

1 import cv2 as cv
2
3 def total_frames(file_name):
4     cap = cv.VideoCapture(file_name)
5     res = 0
6
7     while True:
8         ret, img = cap.read()
9
10        if not ret:
11            break
12
13        res = res+1
14
15    return res
16
17 file_name = "pedestrian.mp4"
18 tot_frame = total_frames(file_name)
19 print(f"Total Frames in {file_name} are {tot_frame}")

```

Listing 2: A Sample Code To Count No. Of Frames in a Video

3. Detecting People

- For this we decided to go with the You Only Look Once (YOLO) algorithm for object detection. The algorithm itself is discussed a bit later in the report.
- We did not train the object detection neural network model ourselves. We used the prebuilt model, trained by the Darknet team because of time constraints.

```

1 import cv2 as cv #OpenCV Library
2 import numpy as np #for handling arrays
3
4 # Give the configuration and weight files for the model and load the network.
5 net = cv.dnn.readNetFromDarknet('yolov3.cfg', 'yolov3.weights') # Reads Network from .cfg
       and .weights
6 net.setPreferableBackend(cv.dnn.DNN_BACKEND_CUDA) # this specifies what type of hardware
       to use (GPU or CPU)
7 net.setPreferableTarget(cv.dnn.DNN_TARGET_CUDA) # sets preferable hardware
8
9 threshold = 0.75
10 nms_threshold = 0.012
11 distance_px=120 # arbitrary value for now but looked best
12
13 def object_detection_YOLO(img,threshold,nms_threshold):
14     # determine the output layers
15     ln = net.getLayerNames()
16     ln = [ln[i[0] - 1] for i in net.getUnconnectedOutLayers()]
17     # construct a blob from the image
18     # blob is just a preprocessed image
19     blob = cv.dnn.blobFromImage(img, 1/255.0, (416, 416), swapRB=True, crop=False)      #
       blob = boxes
20     # blobs goes as the input to YOLO
21     # inputting blob to the Neural Network
22     net.setInput(blob)
23     # t0 = time.time()
24     outputs = net.forward(ln) # finds output
25     # t = time.time()
26     # print('time=', t-t0)
27
28     boxes = []
29     confidences = []
30     centroids = []
31     results = []
32
33     h, w = img.shape[:2]
34     for output in outputs: # Outputs have all the detection and their probability for every
       class

```

```

35     for detection in output:    # detection is the the list of all probabilities with
36         box dimension in start
37         scores = detection[5:]  # everything in array after 5th element
38         classID = np.argmax(scores)      # picks the maximum probability
39         confidence = scores[classID]
40
41         if (confidence > threshold) and (classID == 0):
42             #first 4 elements are box characteristics normalized to range(0,1)
43             #first two element are middle co-ordinate
44             # next two are width and height of blob
45             box = detection[:4] * np.array([w, h, w, h])
46             (centerX, centerY, width, height) = box.astype("int")    # typecasting to int
47             , as array indexes are int
48             x = int(centerX - (width / 2))      # finding upper corner
49             y = int(centerY - (height / 2))
50             box = [x, y, int(width), int(height)]  # changing origin to top left and
51             typecasted to int
52             boxes.append(box)                  # added the box to boxes
53             confidences.append(float(confidence)) # added confidence to confidences
54             centroids.append((centerX,centerY))
55
56             indices = cv.dnn.NMSBoxes(boxes, confidences,score_threshold=threshold,nms_threshold=
57             nms_threshold)
58             # score_threshold -> threshold for confidence
59             # nms_threshold -> threshold for how close to blobs are, if two blobs are too close, one
60             # of them is discarded
61             # closeness is determined by IoU (intersection over Union)
62             # discarding is based on confidence, higher confidence is retained
63
64             boxes_final=[]; confidences_final=[]; centroids_final=[]
65             if len(indices):
66                 for i in indices.flatten():
67                     # extract the bounding box coordinates
68                     x, y = (boxes[i][0], boxes[i][1])
69                     w, h = (boxes[i][2], boxes[i][3])
70                     boxes_final.append((x,y,w,h))
71                     confidences_final.append(confidences[i])
72                     centroids_final.append(centroids[i])
73
74     return boxes_final,confidences_final,centroids_final

```

Listing 3: Our Implementation of Object(Human) Detection using YOLO. label

4. Measuring distance between each couple

- This was undeniably the toughest part of the project and took the longest time. First we decided to go with measuring the distance between the centroids of every two detections. But that may not work in every condition since it depends on the placement of camera and the view angle from the ground and perpendicular to the ground.
- A conversion of the 3-dimensional footage being fed to the algorithm to 2-dimensions was more than necessary to get the top view of every frame to avoid the *viewing angle problem*.

- Enter **Bird's Eye View (BEV)**. This is what we called the top view of every frame. This was made possible by OpenCV's `getPerspectiveTransform()` and `warpPerspective()` functions.

```

1 def birds_eye_view(corner_points, width, height, image):
2     """
3         Compute the transformation matrix
4         corner_points : 4 corner points selected from the image
5         height, width : size of the image
6         return : transformation matrix and the transformed image
7     """
8
9     # Create an array out of the 4 corner points
10    corner_points = np.float32(corner_points)
11
12    # Create an array with the parameters (the dimensions) required to build the matrix
13    img_params = np.float32([[0,0],[width,0],[0,height],[width,height]])
14
15    # Compute and return the transformation matrix
16    matrix = cv.getPerspectiveTransform(corner_points, img_params)
17    img_transformed = cv.warpPerspective(image, matrix, (width, height))
18
19
20    return matrix, img_transformed

```

Listing 4: Function Bird's Eye Perspective Transformation Matrix

- This piece of code essentially calculates what is called a *transformation matrix*[2] for the supplied image (frame) which can then be used to get the centroids of the points as seen from a vertical position directly above the center of the rectangle passed to the function.

```

1 def birds_eye_point(matrix, centroids):
2     """
3         Apply the perspective transformation to every ground point which have been detected
4             on the main frame.
5         @ matrix : the 3x3 matrix
6         @ centroids : list that contains the points to transform
7         return : list containing all the new points
8     """
9
10    # Compute the new coordinates of our points
11    points = np.float32(centroids).reshape(-1, 1, 2)
12    transformed_points = cv.perspectiveTransform(points, matrix)
13
14    # Loop over the points and add them to the list that will be returned
15    transformed_points_list = list()
16
17
18    for i in range(0,transformed_points.shape[0]):
19        transformed_points_list.append([transformed_points[i][0][0],transformed_points[i]
20            [0][1]])
21
22
23    return transformed_points_list

```

Listing 5: Function which convert co-ordinates to it's bird's view co-ordinate

- We used these functions to get a two dimensional view of every frame and calculate distance between every pair of detections (people).

5. Mark the violations

This was again a fairly easy step. We just needed the coordinates of the people in the *violation zone* and make their detection rectangle red as opposed to green.

```

1 import cv2 as cv #OpenCV Library
2 import numpy as np #for handling arrays
3 #from tqdm.std import tqdm #for system progressbar
4 from tqdm.notebook import tqdm #for google colab progressbar
5 from scipy.spatial import distance #for cdist
6 from time import time # for testing purposes
7

4.3 The YOLO Algorithm

4.3.1 What is YOLO Algorithm?

- **YOLO (“You Only Look Once”)**^{[3][4]} is an effective real-time **object recognition** algorithm, first described in the seminal 2015 paper by Joseph Redmon et al.
- **Image Classification** done by YOLO algorithm aims at assigning an image to one of a number of different categories (e.g. car, dog, cat, human, etc.), essentially answering the question “What is in this picture?”. One image has only one category assigned to it.
- **Object Localization** then allows us to locate our object in the image, so our question changes to “Where is it?”.
- **Object Detection** provides the tools for doing just that – finding all the objects in an image and drawing the so-called bounding boxes around them.

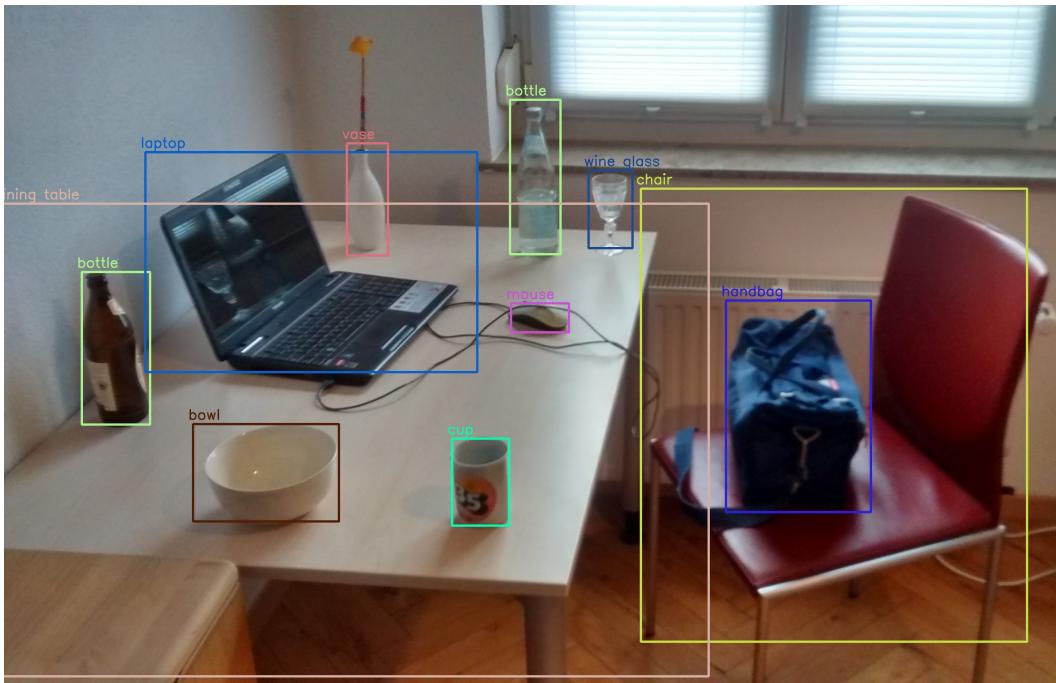

Figure 7: Sample Output Of YOLOv3

4.3.2 Different Types Of *Object Detection Algorithms*

There are a few different algorithms for object detection and they can be split into two groups:

1. Algorithms based on Classification

They are implemented in two stages. First, they select regions of interest in an image. Second, they classify these regions using convolutional neural networks. This solution can be slow because we have to run predictions for every selected region. A widely known example of this type of algorithm is the Region-based convolutional neural network (RCNN) and its cousins Fast-RCNN, Faster-RCNN and the latest addition to the family: Mask-RCNN. Another example is RetinaNet.

2. Algorithms based on Regression

Instead of selecting interesting parts of an image, these predict classes and bounding boxes for the whole image in one run of the algorithm. The two best known examples from this group are the **YOLO (*it stands here*)** family algorithms and SSD (Single Shot Multibox Detector). They are commonly used for real-time object detection as, in general, they trade a bit of accuracy for large improvements in speed.

4.3.3 How does YOLO work? [5]

To understand the YOLO algorithm, it is necessary to establish what is actually being predicted. Ultimately, we aim to predict a class of an object and the bounding box specifying object location. Each bounding box can be described using four descriptors:

1. Center of a bounding box (b_x, b_y)
2. Width (b_w)
3. Height (b_h)
4. Value corresponding to the class of an object (car, person, traffic lights etc)
5. The probability that there is an object bounding the box (p_c)

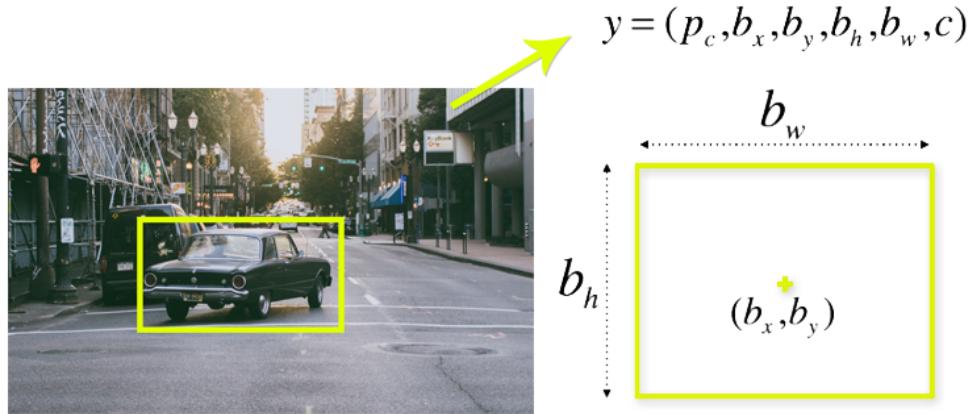

Figure 8: Descriptions of a Bounding Box

Then, the image is split into cells, typically using a 19×19 grid. Each cell is responsible for predicting 5 bounding boxes (in case there are multiple objects in this cell). Therefore, we arrive at a large number of 1805 bounding boxes for one image.

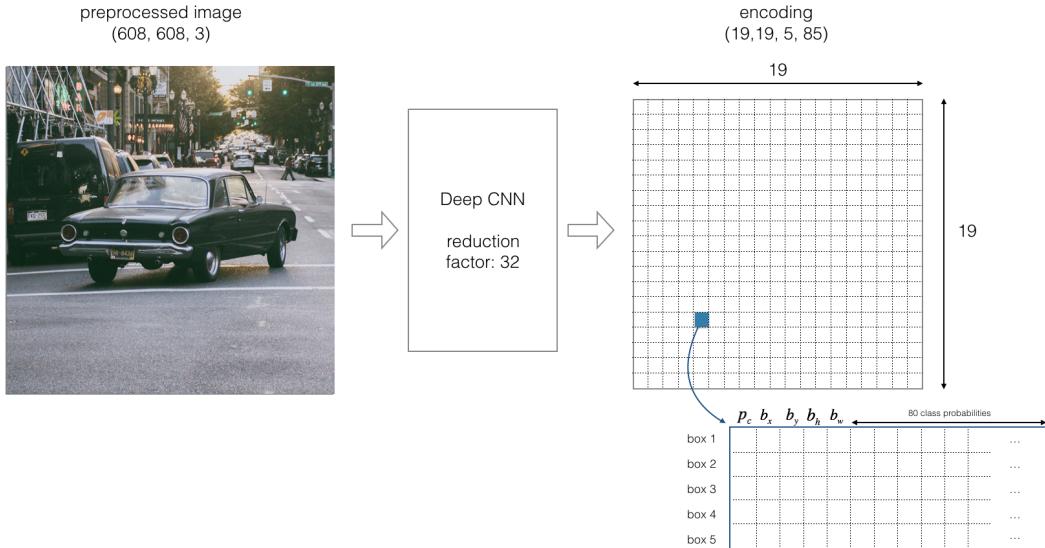

Figure 9: Cell Structure of an Image

Most of these cells and bounding boxes will not contain an object. Therefore, the value p_c is predicted, which serves to remove boxes with low object probability and bounding boxes with the highest shared area in a process called **non-maxima suppression**.

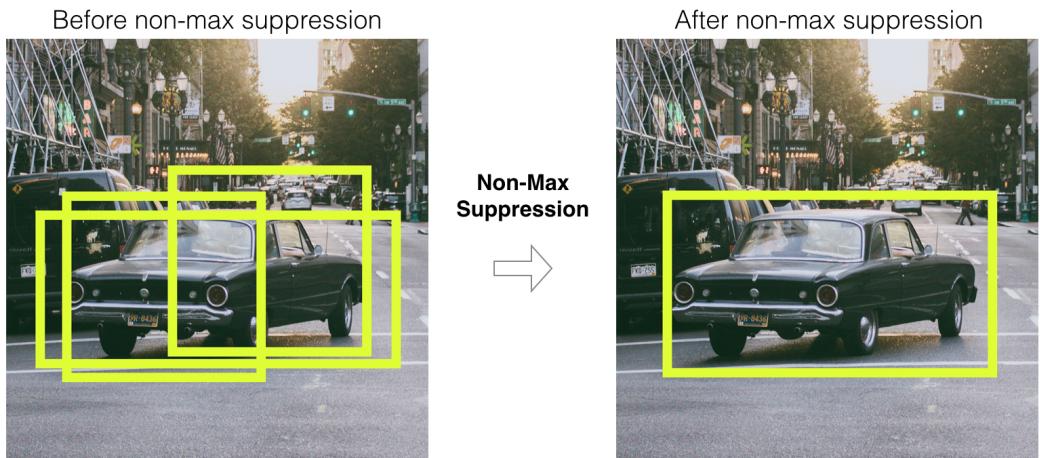

Figure 10: Non-Maxima Suppression

4.4 Darknet implementation of YOLO

There are a few different implementations of the YOLO algorithm on the web. Darknet is one such open source neural network framework. Darknet was written in the C Language and CUDA technology, which makes it really fast and provides for making computations on a GPU, which is essential for real-time predictions.

The Darknet YOLO model that we used here is pre-trained on the COCO (Common Objects in Context) dataset. It can be downloaded [here](#)

5 SHORTCOMINGS

Like every other piece of software, this *checker* is not perfect. It has its own limitations and shortcomings.

1. **The camera that will record the feed needs to be placed at a position high enough** so that the *viewing angle problem* can be avoided. Placing the camera at a horizontal level will not allow the checker to work correctly. For the lowest error margin, the camera needs to be placed perpendicular to the ground, which is not always possible.
2. **Enormous amount of computing power will be needed to make the algorithm work for a live footage.** Even for recorded footage, we were not able to get more than 5-7 frames per second with a decent GPU. This is due to the object detection algorithm taking time in detecting objects. It is not practical to use this *checker* on a live feed.
3. **The minimum social distance needs to be known in pixels beforehand.** This is a lot more difficult than it sounds since a small change in viewing angle can bring a large change in the distance measurements. Plus it is not easy to calculate any distance in pixels. We ourselves have taken arbitrary values using trial and error here to make things work as they should.
4. **The algorithm will completely fail in overly populated areas.** This is due to how YOLO works. It sacrifices accuracy for speed, therefore it really struggles with multiple objects in a single *cell*.

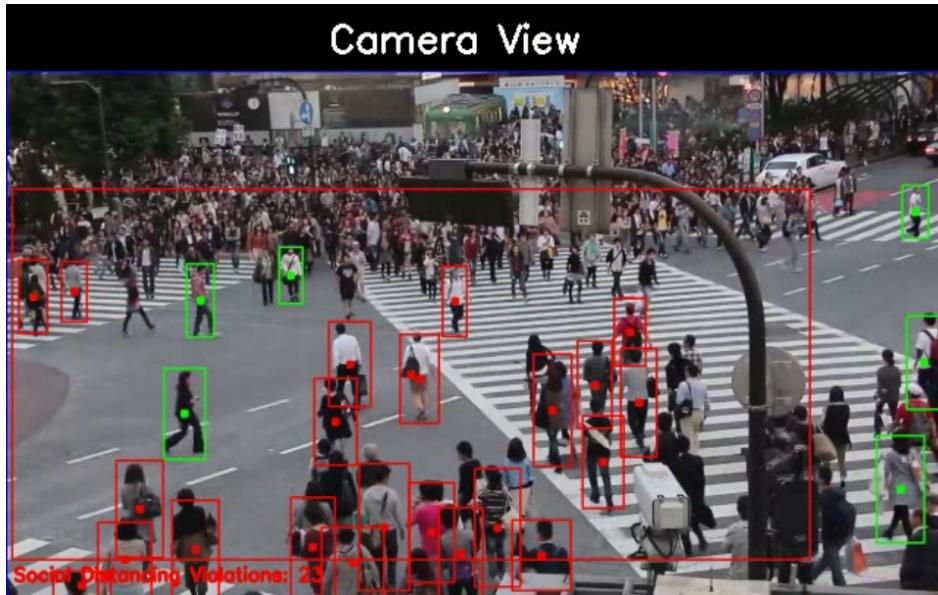

Figure 11: An Example Photo Of YOLO Object Detection Failing.
The Big Red Box should not show as output

5.1 Solutions

A few of these limitations can be solved by adopting the following means:

1. Recording via a drone can completely eliminate the *viewing angle problem*, since a drone can be stabilized at exactly 90 degrees to the ground. Indoors, a camera at the center of the ceiling will work wonders.
2. The *checker* can work in densely populated areas as well if we use RCNN or any classification based algorithm. But that will further slow down the *checker* since RCNN is a much slower algorithm than YOLO.

3. Non-Maxima Suppression Analysis

- To make the algorithm work in relatively dense and overpopulated areas, we were suggested to adjust the Non-Maxima Suppression (NMS) threshold by Prof. Samit Biswas.
- So we decided to try various different values of the NMS threshold. A few of the terms that we used in our NMS analysis are:
 - **Bad Frame:** This is a frame in which the algorithm fails to correctly identify people and instead gives a horrible big box as the output.
 - **Total Frames:** This is the number of total frames in the entire video or the length of the video to be analysed.
 - **Performance Ratio:** This is simply (Number Of Bad Frames)/(Total Frames)
 - **Object Threshold:** This is the confidence value for which a detection is actually considered. Any detection with confidence p_c equal to or above this value is taken into consideration.
- From this it was clear that the threshold value for which the Performance Ratio will be the lowest would be the best value. We also tinkered with the Object Threshold to get the best possible outcome. The script that we wrote for this was:

```

1 file_name = "shibuya_100frames.mp4"
2
3 object_thresholds = [0.25,0.5,0.75,0.85,0.95]
4 nms_thresholds = np.linspace(0.01,0.025, 30)
5
6 plt.figure("NMS vs Performance",figsize=(15,15))
7 plt.xlabel("NMS Threshold")
8 plt.ylabel("Performance Ratio ( Bad Frames / Total Frames )")
9 value = 1
10
11 for object_threshold in object_thresholds:
12     performance_ratios = []
13     for nms_threshold in nms_thresholds:
14         clear_output()
15         print(f"{value}/{5*30}")
16         performance_ratios.append(performance_ratio(object_threshold,nms_threshold,file_name))
17     value = value+1
18     plt.plot(nms_thresholds,performance_ratios,linestyle = '--',marker = 'o',label = f"Obj_Thr = {object_threshold}")
19
20 plt.legend(loc = "best")
21 plt.savefig("NMS vs Performance")
22 plt.show()

```

Listing 7: NMS Analysis for "shibuya_100frames.mp4"

- After running the test for a number of threshold values, we got this graph:

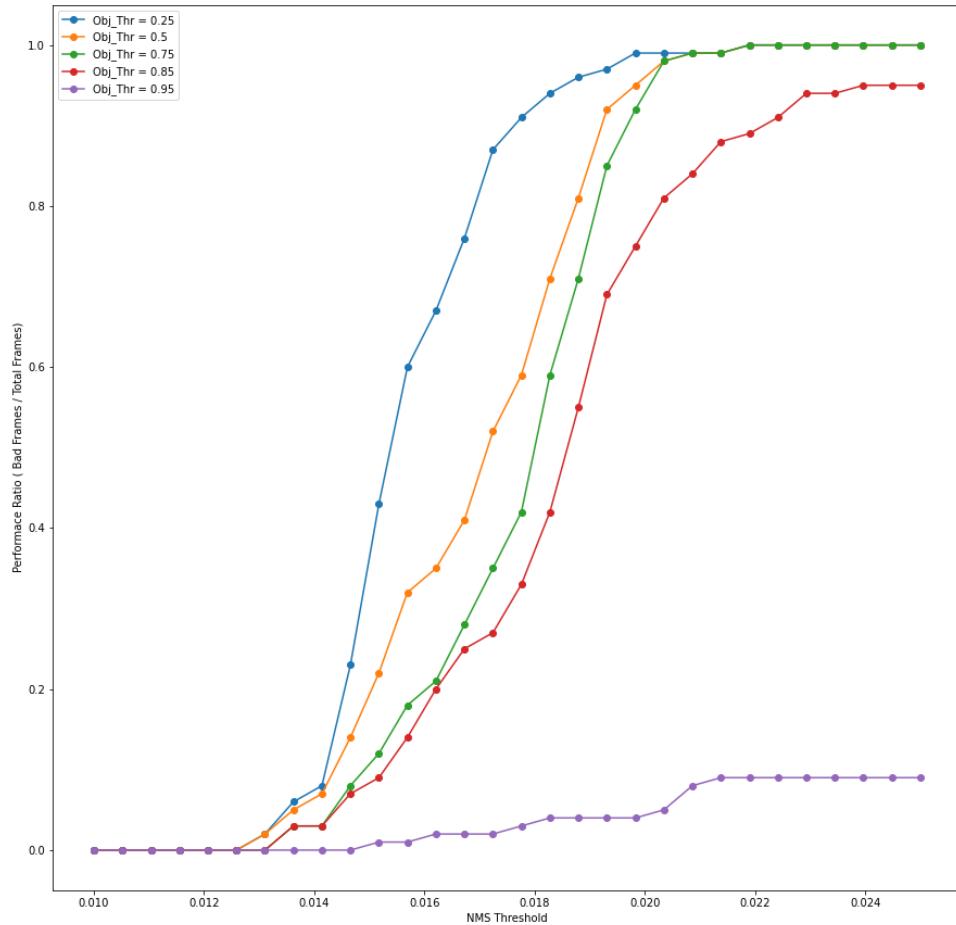

Figure 12: NMS vs. Performance Ratio

- From this, we can see that the algorithm gives the best results for NMS threshold around 0.010 to 0.014 and for the Object threshold greater than 0.9.
- Of course, this is not ideal since **it will ignore most of the detections**.
- So we found a sweet spot at NMS threshold as 0.012 and Object Threshold as 0.75
- It should be noted that this Analysis will be different for different Camera Feeds.

6 HENCEFORTH

While keeping the limitations in mind, this app does serve well as a starting point for an automated social distance checker. The tedious process that needed to be done manually can now be done by a software. This is undoubtedly music to the ears of any software developer and enthusiast.

With that being said, here is how we can improve the *checker*:

1. We can make the entire thing command line based so that an average consumer will not have to dig around the code to calibrate the algorithm to his or her needs.
2. We can (and will) train our own model of YOLO that will only be used to detect people. This can tremendously increase the speed and bring down the processing power requirements
3. We can add a help panel for first time users.
